

Writeup Template

You can use this file as a template for your writeup if you want to submit it as a markdown file, but feel free to use some other method and submit a pdf if you prefer.

Advanced Lane Finding Project

The goals / steps of this project are the following:

- * Compute the camera calibration matrix and distortion coefficients given a set of chessboard images.
- * Apply a distortion correction to raw images.
- * Use color transforms, gradients, etc., to create a thresholded binary image.
- * Apply a perspective transform to rectify binary image ("birds-eye view").
- * Detect lane pixels and fit to find the lane boundary.
- * Determine the curvature of the lane and vehicle position with respect to center.
- * Warp the detected lane boundaries back onto the original image.
- * Output visual display of the lane boundaries and numerical estimation of lane curvature and vehicle position.

Writeup / README

Camera Calibration

1. Briefly state how you computed the camera matrix and distortion coefficients. Provide an example of a distortion corrected calibration image.

The code for this step is contained in the second code cell of the IPython notebook located of the file called `'some_file.py'`.

I start by preparing "object points", which will be the (x, y, z) coordinates of the chessboard corners in the world. Here I am assuming the chessboard is fixed on the (x, y) plane at z=0, such that the object points are the same for each calibration image. Thus, `'objp'` is just a replicated array of coordinates, and `'objpoints'` will be appended with a copy of it every time I successfully detect all chessboard corners in a test image. `'imgpoints'` will be appended with the (x, y) pixel position of each of the corners in the image plane with each successful chessboard detection.

I then used the output `'objpoints'` and `'imgpoints'` to compute the camera calibration and distortion coefficients using the `'cv2.calibrateCamera()'` function. I applied this distortion correction to the test image using the `'cv2.undistort()'` function and obtained this result:

Pipeline (single images)

1. Provide an example of a distortion-corrected image.

To demonstrate this step, I will describe how I apply the distortion correction to one of the test images like this one:

Original Image

Undistorted Image

2. Describe how (and identify where in your code) you used color transforms, gradients or other methods to create a thresholded binary image. Provide an example of a binary image result.

I used a combination of color and gradient thresholds to generate a binary image (thresholding steps at cells 7 through 10 in `'some_file.py'`). Here's an example of my output for this step. (note: this is not actually from one of the test images)

Original Image

combined image

3. Describe how (and identify where in your code) you performed a perspective transform and provide an example of a transformed image.

The code for my perspective transform includes a function called `'warper()'`, which appears in the 3rd code cell of the IPython notebook `'some_file.py'`. The `'warper()'` function takes as inputs an image (`'img'`), as well as source (`'src'`) and destination (`'dst'`) points. I chose the hardcode the source and destination points in the following manner:

```
python
src = np.float32(
    [
        [(img_size[0] / 2) - 55, img_size[1] / 2 + 100],
        [((img_size[0] / 6) - 10), img_size[1]],
        [(img_size[0] * 5 / 6) + 60, img_size[1]],
        [(img_size[0] / 2 + 55), img_size[1] / 2 + 100]]
)
dst = np.float32(
    [
        [(img_size[0] / 4), 0],
        [(img_size[0] / 4), img_size[1]],
        [(img_size[0] * 3 / 4), img_size[1]],
        [(img_size[0] * 3 / 4), 0]]
)
```

This resulted in the following source and destination points:

Source	Destination
585, 460	320, 0

```
| 203, 720 | 320, 720 |
| 1127, 720 | 960, 720 |
| 695, 460 | 960, 0 |
```

I verified that my perspective transform was working as expected by drawing the `src` and `dst` points onto a test image and its warped counterpart to verify that the lines appear parallel in the warped image.

4. Describe how (and identify where in your code) you identified lane-line pixels and fit their positions with a polynomial?

Then I did some other stuff and fit my lane lines with a 2nd order polynomial kinda like this:

5. Describe how (and identify where in your code) you calculated the radius of curvature of the lane and the position of the vehicle with respect to center.

I did this in 18th code cell of the IPython notebook in `some_file.py`

6. Provide an example image of your result plotted back down onto the road such that the lane area is identified clearly.

I implemented this step 20th code cell of the IPython notebook in `some_file.py`. Here is an example of my result on a test image:

Pipeline (video)

1. Provide a link to your final video output. Your pipeline should perform reasonably well on the entire project video (wobbly lines are ok but no catastrophic failures that would cause the car to drive off the road!).

Here's a [link to my video result](./project_video_out6.mp4)

https://github.com/mailmerifath/AdvancedLaneFinding/blob/master/project_video_out6.mp4

Discussion

1. Briefly discuss any problems / issues you faced in your implementation of this project. Where will your pipeline likely fail? What could you do to make it more robust?

To make the pipeline better, I tried masking technique learned in the finding lanes project but it didn't come out good for me. Also, in the challenge video, the current pipeline fails in some part. I think because of lots of distortion like shadows and other things. If I manipulate parameters with distortion, I think the pipeline can be more robust than the current one.
